Of a remedy, not acting immediately or directly. See *P. CAUTERY*. 2. As a n., the algebraic sum of the amount of work which may be obtained at any point from the mutual repulsion of the electricities in a system until they are at an infinite distance apart and the amount obtained from a unit quantity of positive electricity placed at that point. Thus the sign is the same as that of the electrification of the system to which the p. is due. This energy becomes kinetic as the electricities are brought to approach one another. [a, 49.] The ability of an electrified body to do work by virtue of its electrification; hence the degree of its electrification as compared with some other body with which it is connected in the same circuit, and especially as compared with the earth. Differences in p. are the cause of electric currents; for, whenever two bodies differing in p. are connected by a conductor, a current passes from the body having the higher p. to the one having a lower p. until the p's are equalized. [B.]—**Electric p.** See *P. (3d def.)*.—**Static p.** The difference in electric level between the earth and a body charged with static electricity. [B.]

The complex jelly-like, proteid living substance of animals and plants which, in its undifferentiated stage, is capable of nutrition, growth, movement, and reproduction. The term was introduced independently by Purkinje (1839 to 1840) and von Mohl (1844). P. usually occurs in minute, more or less distinct masses, called cells (q. v.), and, by becoming specially differentiated in structure, gives rise to a specialization of function whereby the originally homogeneous p. is capable of performing all the varied functions of the most highly organized animals and plants. In its youngest or formative period, p. is of a homogeneous structure, but very soon divides into a denser part, which assumes a granular, filar, or reticular arrangement, and a semi-fluid, homogeneous matrix, the *paraplasma*. According to Heitzmann and Elsberg, the protoplasmic fibrils forming the reticula of neighboring cells are interconnected, so that there are no independent cells or plastids except the wandering cells and those of the blood and lymph. [J, 26, 31, 39.] 2. Of Schultze (1861) and many more recent writers, the cell-body only. **RESPIRATION**, n.  $\text{Re}^2\text{-spi}^2\text{-r-a}^2\text{-shu}^2\text{n}$ . Gr., *ἀναπνοή, ἀνάπνευσις*. Lat., *respiratio* (from *respirare*, to breathe). Fr., r. Ger., *R. Athmen, Athmung, Athem*. 1. The mechanical processes of inspiration and expiration of air, or of supplying water to the gills, etc. 2. One complete inspiration followed by a complete expiration. 3. The taking up of oxygen and the giving off of carbon dioxide by the tissues of animals or plants; that part of the nutrient process which has to do with nutriment and waste in the gaseous form. 4. The assumption of oxygen by the blood in the lungs, gills, etc., and the rejection of carbon dioxide, watery vapor, and traces of organic matter at the same time and by the same organs (see *External r.*). 5. Of less recent writers, the taking up of carbon dioxide and the rejection of oxygen by the green parts of plants in sunlight; shown by Draper (1844) to be comparable to digestion, but not to. Physiologists are now agreed that the r. of plants is identical with that of animals, and the term is used collectively for the processes of absorption of oxygen by plants, oxidation of the oxidizable organic matter (carbohydrates) in their tissues, and evolution of the products (carbonic acid and water) of such oxidation. [B, 229, 291 (a, 35); J, 40.]—**Abdominal r.** Fr., *abdominale* (ou ventrale). Ger., *Abdominalathmen, Bauchathmen*. R. (1st def.) due principally to the contraction of the diaphragm and the elasticity of the abdominal walls and viscera; said to be common in adult men, the horse, the cat, and the rabbit. [J, 14, 40.]—**Aerial r.** Fr., *aérienne*. Ger., *Luftathmung*. R. of air, in which the respiratory membrane of the lungs, trachea, etc., is supplied with oxygen and relieved of carbon dioxide by means of atmospheric air. In the lower forms of air-breathing animals, aerial r. is combined with aquatic r., as in frogs, or the animal may exercise either aerial or aquatic r. as inclination or necessity demands, like frogs in winter and some pulmonate gastropods. [J, 5, 11.]—**Aquatic r.** Ger., *Wasserathmung*. R. in water, i. e., r. in which the respiratory membrane, branchial mucosa (gills), skin, etc., are supplied with oxygen and relieved of carbon dioxide by means of water. [J.] Cf. *Aerial r.*—**Artificial r.** Ger., *künstliche Athmung*. 1. Imitation of the natural movements of r., as by alternately drawing the arms up over the head and pressing them against the sides of the chest, thus in turn enlarging the thoracic cavity by elevating the ribs and diminishing it by depressing them, as in Sylvester's method of resuscitating asphyxiated persons. The expiration may be made more complete by pressing the abdominal wall toward the thorax at the same time that the chest is compressed. [J.] Hall's method (the so-called "ready method") of treating asphyxia consists in laying the person on the face to allow liquids to run out from the air-passages, then turning him on one side, so as to allow of the expansion of the walls of the chest from the weight of the body having been removed from the breast. These movements are repeated fifteen times to the minute, and warm applications are made. Howard's method is by the direct application of compression to the ribs by the hands of the operator, who kneels over the patient, slowly brings his weight to bear upon the chest, compressing the ribs and costal cartilages, and then suddenly removes the pressure, allowing the thorax to expand by its own elasticity. [E.] 2. See *Forced r.*—**Blood-r.** Ger., *Blutathmung*. See *External r.*—**Blowing r.** See *Bronchial r.*—**Branchial r.** Ger., *Kiemenathmung*. R. by means of gills or branchiae, as in aquatic animals. [J.]—**Branchial r.** Fr., *souffle branchique, bruit des bronches*. Ger., *Bronchialathmen, Bronchialgeräusch*. 1. The sound produced by the rush of the air from the larynx into the pharynx or the reverse; most marked in expiration. A somewhat similar sound may be heard over the bronchial tubes. [J, 40.] 2. A form of r. which displaces vesicular r. in certain diseases of the lungs. In inspiration it is tubal, short in duration, incomplete, and of high pitch. Expiration is, as long as inspiration or longer, of greater intensity, and of higher pitch. It indicates condensed lung tissue, as in pneumonia, pleurisy with effusion, etc. [D, 1.] See also *BRONCHIAL MURMUR*.—**Broncho-vesicular r.** Of Flint, r. which shows less of the vesicular character than the healthy respiratory murmur, less softness, higher pitch, and more of a blowing and less of an equable character. The inspiratory portion is short in duration, elevated in pitch, and variable in intensity. The expiratory portion is either absent or, if present, prolonged, higher in pitch, and often of greater intensity than the inspiratory portion, which it follows after an appreciable interval. It indicates pulmonary condensation, and may occur in

phthisis, pneumonia, cancer, cedema, etc. [D, 1.]—**Buccal r.** See *Mouth-BREATHING*.—**Cavernous r.** R. accompanied by a sound like that produced by blowing into a cavity. In inspiration it is slow in its development and low in pitch; in expiration it is still lower in pitch. It indicates a cavity or a globular tracheal dilatation. [D, 1.]—**Cerebral r.** See *Nervous r.*—**Cheyne-Stokes r.** Ger., *Cheyne-Stokes'sches Phänomen* (oder *Athmungsphänomen*). An abnormal state of the r. observed when death is impending, and in certain diseases, especially of the brain, first carefully investigated by Cheyne and Stokes. The respiratory movements gradually decrease in extent and rapidly, finally ceasing entirely for several seconds, then begin again and gradually increase until the normal condition is regained or exceeded. [J, 19.]—**Clavicular r.** A form of r. practised by singers in which the clavicle takes part in the respiratory movement, the shoulders being elevated. ["Rev. de laryng. et d'otol." May 15, 1892, p. 292 (a, 50).] Cf. *Costo-superior r.*—**Cogged-wheel r.** See *Interrupted r.*—**Costal r.** Ger., *Costalathmen, Rippenr.* R. (1st def.) due chiefly to the elevation and depression of the ribs, especially the upper ones, the diaphragm taking a comparatively small part; seen especially in women and supposed by most physiologists to have reference to gestation, although some attribute it to the mode of dress. [J, 8, 19, 28, 40, 41.]—**Costo-inferior r.** Of Beau and Maissiat, r. (1st def.) produced mainly by the elevation and depression of the lower ribs; said to be especially well seen in dogs. [J, 18, 28, 45.]—**Costo-superior r.** Of Beau and Maissiat, a form of respiratory movement produced mainly by the elevation and depression of the upper ribs; most common in women. See *Abdominal r.*—**Direct r.** R. in which the living matter is usually in small bulk, as in the *Amaba*, etc., takes oxygen directly from the surrounding medium, and excretes carbon dioxide directly into it. [J, 55.]—**Divided r.** [Walshe]. That form of r. in which there is a distinct interval between the murmur of inspiration and that of expiration; due to dilatation of the air-cells (as in emphysema), by which the expulsion of the air is hindered. [D, 1.]—**Exaggerated r.** R. which differs from normal r. only in showing greater intensity. It may, however, become a sign of disease, in which case the excess of intensity is in expiration, in health it is in inspiration. [Walshe and Fournet (D, 11).]—**External r.** Ger., *äussere Athmung, Blutathmung*. The assumption of oxygen and rejection of carbon dioxide carried on by the blood in its passage through the lungs, branchiae, or other respiratory membranes. The oxygen is conveyed by the blood to the entire body, and while in the capillaries the blood gives up its oxygen to the tissues and receives carbon dioxide in return. So far as general r. is concerned, the blood acts simply as a carrier of oxygen and carbon dioxide for the tissues. Considered as a tissue, however, the blood respires like other tissues. [J.] See *Tissue r.*—**Extrinsic r.** Of F. Hewitt, the inspiration and immediate expiration of a gas (e. g., nitrous oxide) into the surrounding air, so that a portion that has once been inspired is not inspired again. ["Med. Chron." Feb., 1886, p. 363.]—**Facial r.** Ger., *Gesichtathmung*. All the movements of the face dependent upon r., especially the dilatation of the nostrils during inspiration and their collapse during expiration. [D, 47.]—**Fetal r.** See *Placental r.*—**Forced r.** R. supported by blowing air into the lungs with bellows, or in some other way, as in physiological experiments. The nozzle of the bellows is usually connected with the trachea by means of a tube. By using two Y-tubes, one of them communicating in some part of its length with a chamber for ether, chloroform, etc., either pure air or air mixed with the anæsthetic may be made to pass into the lungs. [J.]—**Harsh r.** See *Broncho-vesicular r.*—**Hissing r.** An increase of the vesicular murmur producing a hissing sound. [a, 34.]—**Hollow r.** See *Amphoric MURMUR* (1st def.).—**Indirect r.** R. in which the living matter is usually in quite large masses, as in the higher animals, and the oxygen is supplied by a respiratory blood, which also removes the carbon dioxide. In this form of r. the respiratory blood is in turn supplied with oxygen and relieved of carbon dioxide by special respiratory organs (lungs or gills). [J, 55.]—**Inner r.** **Internal r.** See *Tissue r.*—**Interrupted r.** Fr., *r. saccadée, r. entrecoupée*. In inspiration the glottis is wide open, allowing the freest entrance of the air, while in expiration it is narrowed and somewhat retards the air's exit. [J, 19.]—**Lung r.** See *Pulmonary r.*—**Metamorphotic r.** **Metamorphosing r.** Of Seitz, a respiratory sound that begins like that of stenosis, distinctly bronchial, and suddenly changes to a weak bronchial breathing that is also heard during expiration; very rare and said to be a certain sign of a cavity. [Vierordt (a, 34).]—**Muscle-r.** Ger., *Muskelathmung*. R. (3d def.) by a muscle when in action. [K.]—**Nasal r.** R. (1st def.) through the nose. [J.]—**Nervous r.** Of Corrigan, that form of r. in fevers (especially in typhus) in which the lips are closed, the cheeks are distended, the nostrils dilate with each expiration, the breathing is irregular, and there is a

[D. 1.]—**Normal r.** See *Tranquil r.*—**Oral r.** See *Mouth-BREATHING*.—**Ordinary r.** See *Tranquil r.*—**Periodical r.** See *Periodische ATHMUNG*.—**Pharyngeal r.** 1. The taking up of oxygen and giving off of carbon dioxide by the tissues of the body for their own requirements. In man and the higher animals generally the tissues obtain their oxygen from the blood in the capillaries, and give their carbon dioxide up to it in return, the capillary walls acting as a respiratory membrane to the tissues. In insects the air is conveyed to the tissues by the tracheae, and the tissues respire the oxygen of the air directly, instead of from the blood as in man, etc., the walls of the tracheae acting as a respiratory membrane. In unicellular organisms (*Protozoa*) the general surface of the body acts as a respiratory membrane, and the protoplasm respire the oxygen dissolved in the surrounding water directly. **RHUBARB**, n.  $\text{Ru}^2\text{h}^2\text{a}^2\text{r}^2\text{b}$ . Gr.,  $\rho\acute{\alpha}\rho\eta\omega$ . Lat., *rheum* [U. S. Ph.], *rheubarbarum* (i. e., *rheum barbarum*, foreign rhubarb), *radix rhei* [Ger. Ph., Dan. Ph., Belg. Ph., Norw. Ph., Swed. Ph., Russ. Ph., Swiss Ph.], *rhei radix* [Br. Ph., Gr. Ph.], *r. (radicis segmenta)* [Hung. Ph., 2d ed.], *r. (radix)* [Austr. Ph., Netherl. Ph.], *rhizoma rhei* [Finn. Ph.], *r. rhubarbe (de Chine, ou de Moscovie, ou de Perse)* [Fr. Cod.], Ger., *Rhabarber*, *Rhabarberwurzel*. Sp., *ruibarbo* (*rhizoma o tallo aéreo*) [Sp. Ph.]. 1. Of the U. S. Ph., the root of *Rheum officinale* and other undetermined species of *Rheum*; of the Br. Ph., the sliced and dried root of "*Rheum palmatum*", *Rheum officinale*, and probably other species, collected and prepared in China and Thibet. "The botanical source of the commercial drug (see *Chinese r*) has not been definitely ascertained, the various species supposed to yield it producing under cultivation in Europe roots lacking some of the characteristics of the Chinese drug. The differences, however, may be due to climate. R-root contains chrysophan, rheotannic acid, emodin, a neutral substance,  $\text{C}_{10}\text{H}_{12}\text{O}_4$ , forming colorless crystals, several resins (see *APORRHETIN* and *EURYTHORRHETIN*), an albuminoid principle insoluble in alcohol but soluble in water, mucilage (1 to 17 per cent.), extractive, tannic and gallic acids, sugar, starch, pectin, lignin, calcium oxalate, and various inorganic salts. All varieties of r-root have the properties, though in a lesser degree, of the Chinese drug. It is purgative and cholagogue, and in small doses (from 5 to 10 grains) a mild laxative and stomachic tonic. It is useful in dyspepsia attended with constipation or with deficient biliary and intestinal secretions, in cholera infantum, and in chronic dysentery, and is of special value in duodenal catarrh or catarrh of the biliary ducts with jaundice and in certain skin diseases. It is also applied in powder to indolent and sloughing ulcers. It is most effectual in substance,

though the fluid extract, infusion, syrup, and tincture are also used, being combined with soap in cases in which it is necessary to counteract its astringency. 2. The genus *Rheum*. [B. 5, 180 (a, 35).] For the preparations, see the corresponding Latin forms under *Rheum*.—**Austrian r.** See under *German r.*—**Banbury r.** See under *English r.* (2d def.).—**Batavian r.** A variety of Chinese r. prepared so as to resemble Russian r. The pieces are of a less bright color than the Russian drug, and are pierced through with perforations, which are often concealed, however, by being filled with the powdered root. [B. 5 (a, 35).]—**Bucharian r.** 1. The *Rheum undulatum*; so called because formerly believed to furnish Russian r. 2. Russian r. 3. The Chinese r. of the Russians; an inferior variety of r.-root imported into Russia from Tartary. [B. 180 (a, 35).]—**Canton r., China r., Chinese r.** Lat., *rheum sinense* (seu *indicum*). Fr., *rhubarbe de Chine* [Fr. Cod.]. Ger., *chinesischer* (oder *dinischer*, oder *holländischer*, oder *ostindischer*, oder *tatarischer*) *Rhabarber*. Sp., *rubarbo de China* [Mex. Ph.]. R.-root as now known to commerce. It occurs in cylindrical, or barrel-shaped, or plano-convex, or conical, or irregular-shaped pieces, of a peculiar aromatic odor and a bitter, astringent taste; they average about 3 or 4 inches in length and 2 to 3 inches in width, and are usually sorted as round and flat r. The pieces are somewhat shriveled on the surface, and are pierced with holes in which may be found portions of a string used to suspend the root when drying. The drug when well developed displays, if broken transversely, lines (medullary rays) arranged as an internal ring of stellate spots. When powdered, it is yellow, having a tinge of reddish-brown. It has a gritty taste when chewed, and turns the saliva yellow. There are two varieties of China r.—one, believed to be produced by the *Rheum palmatum*, having a red-grained fracture with white lattice-work veins, and the other, referred to *Rheum officinale*, a black-grained fracture with white veins ramifying longitudinally. For chemical composition and medicinal properties, see under *R.* [B. 5, 180 (a, 35).]—**Compound tincture of r.** See *Tinctura rhei amara*.—**Crown r.** See *Russian r.*—**Decoction of r.** See *Infusum rhei*.—**Dutch r.** Lat., *radix rhei hollandici*. The root of *Rheum rhaponticum* and *R. officinale* cultivated in Great Britain. That from *R. rhaponticum* formerly occurred in two forms, one perforated and the other (*stick r.*) in cylinders. The finest pieces of *Banbury r.* (so called because from *Rheum rhaponticum* cultivated at Bodicot, a village near Banbury) have a good color and display brilliant pink markings when broken. The taste is more mucilaginous and astringent and less bitter than that of Chinese r., and the texture more spongy and soft. [B. 5 (a, 35).]—**European r.** Sp., *rapontico* [Mex. Ph.]. Ger., *französischer Rhabarber*. R. produced in France from *Rheum rhaponticum*, *Rheum undulatum*, *Rheum compactum*, and *Rheum palmatum*. The last-named species, according to Guibourt, affords a root more closely resembling the Chinese drug, but it has been least cultivated, owing to the liability of the central root to premature decay. Except in the vicinity of Avignon and in a few other places, the cultivation of r. in France has been abandoned. [B. 180 (a, 35).]—**Garden r.** The *Rheum rhaponticum*, *Rheum palmatum*, *Rheum undulatum*, or hybrids of these, cultivated for their edible leaf-stalks. [B. 5 (a, 35).]—**German r.** R.-root produced at Austerlitz and Auspitz in Moravia, from *Rheum compactum* and according to Hanbury, *Rheum rhaponticum*; at Ilmitz, Kremnitz, and Frauenkirchen in Hungary from *Rheum rhaponticum*; and in Silesia from *Rheum australe*. Moravian r. is said to be nearly equal, medicinally, to Chinese r. [B. 18 (a, 35).]—**Himalaya r.** A variety produced by *Rheum australe*, *Rheum spiciforme*, *Rheum moorcroftianum*, etc.; said to be nearly equal to Russian r. as a purgative, and superior as an astringent and tonic. The perforations are large, but usually do not extend entirely through the pieces, having been made for inspection only. The powder of this has not the brownish tinge of that of the Chinese drug. [B. 180 (a, 35).]—**Stick r.** See under *English r.* (2d def.).—**Taschkend r.** A variety of Russian r. of inferior quality brought into Russia by way of Taschkend. After its disappearance from commerce the term was transferred to Russian r., with which it was probably identical in botanical origin. [B. 18, 180 (a, 35).]—**White r.** Lat., *radix rhei albi*, *radix rhei imperialis* (1st def.). Fr., *rhubarbe blanche*. Ger., *weisser Rhabarber*. 1. A sweet, milk-white r.-root, once known to Russian commerce, referred to *Rheum leucorrhizum*. It equaled the best r. as a medicine, and is said to have been used exclusively at the Russian Court. 2. The *Convolvulus mechoacantha*, or its root (white jalap). [B. 180 (a, 35).]

**RIB**, n.  $Ri(ru)^{a}n^{a}n^{a}$ . Gr., *ῥιβή*, *ῥιβή*. Lat., *costa*. Fr., *côte*. Ger., *Rippe*. 1. One of the long, flat curved bones with the concavity inward which extend ventrally from the vertical column. Their anterior or ventral extremities are united in the thoracic region by means of the sternum and costal cartilages, and elsewhere are free. They constitute the pleuropophyses of a typical vertebra, and are usually confined to the dorsal and abdominal regions. The vertebral extremities, or heads, are somewhat thickened, and articulate with the bodies of two adjacent vertebrae, the articular surfaces usually being separated by the intervertebral ridges. On the lower margin, separated from the head by a slight constriction, the neck, is the tubercle, which articulates with the transverse process of the lower of the two vertebrae with which the r. articulates. Slightly anterior to the tubercle is the angle, at which point the bone curves more sharply. On the inner aspect of the lower border is a groove for the intercostal vessels and nerves. The anterior extremity is concave for the reception of the costal cartilage. Each r. is twisted upon itself, causing the vertical position behind to be oblique in front. In man the ribs are normally twelve in number on each side, seven true and five false. 2. A r. and its costal cartilage regarded as a unit. [L, 31, 142, 153, 332.] 3. RICINUS COMMUNIS. [A, 327.]

in most tropical and many temperate countries. An annual herb in the temperate latitudes of North America and Europe, it is a shrub or small tree in the warmer regions of the Mediterranean, and in some tropical countries attains a height of 40 feet. Some 16 more or less well-marked forms, some of which are regarded by many botanists as distinct, are maintained by Müller to be one species. The fruit is a capsule of three cells, each cell containing a smooth, shining, ash-colored or grayish seed, of a compressed, ellipsoidal shape, marbled with reddish-brown spots and veins. These seeds (castor-seeds) contain an acid, probably volatile, emetic, powerfully purgative principle, and yield castor-oil. In India, where this oil is extensively produced, there are two varieties of the plant, known respectively as *R. communis fructibus majoribus* and *R. communis fructibus minoribus*, and the latter is thought to furnish the better product. The oil of the large-seeded variety is said to have a heavy, unpleasant odor and a darker color, and is used chiefly in veterinary practice and for burning. The oil of the small-seeded variety is used not only for the purposes referred to under castor-oil (q. v.), but in cutaneous and rectal diseases and as an anthelmintic. The leaves are used as a galactagogue, either applied to the breasts, or given internally; they are also used in skin diseases, abscesses, and ophthalmia. A decoction of the root is used in flatulent colic, for nephritic pains, and in asthma, and the root-bark is said to be powerfully purgative. The plant is cultivated in Germany for the production of silk, one species of silkworm (*Bombyx Arrandi*) requiring its leaves as food. [B, 175, 180, 185, 314 (a, 35).] Cf. It also occurs in the fermentation of palm wine. In ordinary yeast as produced in the high fermentation (between 14° C. and 18° C.) of beer it forms, at the surface of the liquid, branched bands consisting of several buds; in low fermentation (between 4° C. and 10° C.) the yeast is deposited at the bottom of the vessel, the cells being mostly solitary or united in small numbers. If not fully immersed in the liquid, it passes into forms similar to molds, and, like the latter, lives on atmospheric oxygen. These aerobic forms, however, pass again into a. If immersed in wort. In small quantities it is found in the juices of many fruits, grasses, roots, and flowers. It occurs either as large transparent prismatic crystals (rock-candy, sugar-candy), as small, white, prismatic, crystalline granules, or as an amorphous vitreous mass (barley-sugar). It has an agreeable, very sweet taste, and is completely soluble in water, only slightly soluble in alcohol, insoluble in ether. It melts at 160° C., at 200° C. is converted into caramel, and at a higher temperature decomposes into various volatile empyreumatic principles and carbon. Its aqueous solution has a specific dextrorotatory power of 73°. In chemical structure, it is a doubly tetratomic or an octatomic alcohol, and at the same time a double aldehyde. It stands in the same relation to the carbohydrates of the formula  $\text{C}_6\text{H}_{12}\text{O}_6$  (glucoses) that ether does to alcohol. The term is also applied generally to all carbohydrates of the formula  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ . [B. 4, 9.]

[A. 42.]—**Cylindro-s.** A form of tumor produced when sarcomatous tissue undergoes partial hyaline or mucoid degeneration, or when it exists in combination with myomatous formations. Such growths are generally included under the term cylindroma, although this may also be applied to tumors in which the epithelial cells are involved. [Ziegler (a. 25).]

—**Encephaloid s.** Ger., *Rundzellensarkom*. A variety of s. consisting for the most part of simple embryonic cells imbedded in a scanty homogeneous or granular matrix. There are two varieties, the small-celled and large-celled. The tumors are of very rapid growth, often ending fatally in a few months, especially in children. They are soft and pinkish, gray, or yellowish-white, with frequent patches of extravasation. When coming to the surface, they form the so-called fungus hematomas. [E. 25.]—**Fascicular s.** **Fasciculated s.** See *Spindle-celled s.*—**Gelatinous s.** Ger., *Gallert-sarkom*. See MYXOSARCOMA.—**Giant-celled s.** Ger., *Riesenzellensarkom*. A form of s. (2d def.) which generally grows from the cancellous tissue of bone, especially from the jaws and the ends of the long bones. It consists structurally of large round, oval, or branched cells, with many nuclei imbedded in a round-celled or spindle-celled sarcomatous tissue which may undergo mucoid degeneration or become ossified. The tumors are reddish-brown or bluish-red, and may be disseminated over the surface or occur in groups. The older ones undergo absorption with desquamation of the epi-

dermis, leaving finally dark pigmented spots and cicatrices. The disease is attended with the development of marasmus that tends to a fatal termination. [G. 47.]—**Keloidiform s.** A s. (2d def.) developing in the skin and presenting the appearance of keloid. [A. Jacobson, "Arch. f. klin. Chir." xxx, p. 89 (a. 34).]—**Lipomatous s.** Ger., *Fettsarkom*. S. [E. 6.]—**Papillary s.** Cutaneous papillæ, or warts that have undergone transformation into sarcomatous tissue by the growth and multiplication of the cells. [Ziegler (a. 34).]—**Periosteal s.** 1. See CHLOROMA. 2. A fibrous tumor of the periosteum, most frequently seen on the jaws. [E.]—**Pigmented s.** See *Melanotic s.*—**Plexiform s.** A round-celled s. characterized by cylinders or irregular masses of cells, a hyaline or very finely fibrillated substance surrounding these, a polygonal form of cells, and an absence of intercellular material. **SARSAPARILLA** [U. S. Ph.], (Lat.), n. f. Sa<sup>2</sup>rs-a<sup>2</sup>-pa<sup>2</sup>r(pa<sup>2</sup>r)/i<sup>2</sup>-i<sup>2</sup>la<sup>3</sup>. Fr., *salsepareille* (racine *adventive* [Fr. Cod.]). Ger., *Sarsaparille*, *Sassaparill*, oder *Salsaparill*, oder *Sarsaparill*. Wurzel, Heckenrebenwurzel. Sp., *zarzaparrilla* (raíz) [Sp. Ph.]. Of the U. S. Ph., the root of *Smilax officinalis*, *Smilax medica*, and other undetermined species of *Smilax*. The Br. Ph. recognizes the root (dried) of *Smilax officinalis*, and the Mex. Ph. that of *Smilax medica*. Other imperfectly known species, such as *Smilax papyracea* and *Smilax syphilitica*, are also said to be sources of the commercial drug. The roots are cylindrical, fleshy, plump when fresh, and more or less wrinkled longitudinally when dried, have a thick amy-laceous bark, are often beset with thread-like rootlets (beard) of

nearly uniform size, and grow from a thick knotty short root-stock (called *chump*) by the druggists and ordered to be rejected by the U. S. Ph.). They are readily split in the direction of their length owing to the longitudinal fibres of which their ligneous portion is composed. S. displays on cross-section a white central medulla, inclosed by a woody zone of closely packed fibro-vascular bundles with scalariform vessels and lignified procumbent cells. This zone is surrounded by a circle (nucleus sheath) of small cells forming a brown ring between which and the epidermis occurs a tissue (the bark) composed of parenchymatous cells often loaded with starch granules and raphides. S. has a marked odor only in decoction. If chewed for some time, it leaves an unpleasant acriminous impression in the mouth and throat. Though it contains starch, resin, etc., it is believed to owe whatever medicinal properties it may possess to parillin (*q. v.*). It is used in syphilis, chronic rheumatism, scrofula, skin diseases, etc. Its value as an alternative is very doubtful. **SCAMMONY**, n. Ska<sup>2</sup>m-on<sup>2</sup>-i<sup>2</sup>. Gr., *σκαμνία*. Lat., *scammonia, scammonia, scammonium* [U. S. Ph., Br. Ph., Dan. Ph., Gr. Ph., Swiss Ph., Hung. Ph. (1st ed.), Norw. Ph., Swed. Ph.] (*halepense* [Pruss. Ph., 6th ed.]). *resina scammonium, gummi scammonii*. Fr., *scammonée* (d'Alep) [Fr. Cod.], *scammonée de Syrie*. Ger., *Scammonium, Scammonie*. Sp., *escamonea* [Sp. Ph.]. A

gum-resin obtained by incision from the root of *Convolvulus scammonia*. The pure product, dried by exposure to sun and air, is a transparent, brittle substance, breaking with a vitreous, shining fracture. In the fragment it is pale yellowish-brown, and in powder of a light-buff color. It yields by treatment with ether over 88 per cent. of soluble matter, the residuum being almost colorless. If not kept quite dry, it usually becomes moldy, and in course of time develops at the surface a white, crystalline, cauliflower-like efflorescence the chemical nature of which is not known. Most of the s. of the U. S. markets is in circular cakes, 6 inches or less in diameter, and from ¼ to 1½ inch or more thick in the centre, dark olive or dark ash externally, and lighter internally. When fractured, it exhibits usually a finely porous structure. It has a peculiar cheesy smell, and a taste which, though slight at first, leaves a bitterish, acrid sensation. When triturated with water, it gives to the latter a greenish, milky appearance. S. has cathartic properties, due to the presence of jalapin. As its tendency is to gripe, it is usually given with other cathartics, or in emulsion with mucilage, almonds, or some other demulcent. It was used by the ancient Greeks and Arabians not only as a purgative, but externally in various skin diseases. [B, 5, 18, 180 (a, 35).]—**Aleppo s.** Lat., *scammonium halepense* [Pruss. Ph., 6th ed.] (seu *aleppicum*). Fr., *scammonée d'Alep* [Fr. Cod.]. Ger., *aleppisches Scammonium, Scammonium von Halep*. S. shipped from Aleppo; a name formerly given to very pure sorts of s. from that port. To day, at least in the United States, the term is applied to s. of various qualities shipped from Smyrna. [a, 35.]—**Factitious s.** See *Montpellier s.* and under *Smyrna s.*—**French s.** See *Montpellier s.*—**Lacrima s.** The pure drug as prepared near Smyrna by mixing shell s. with the partially dried drops of juice remaining on the cut surface of the root and with a calcareous earth. It occurs in irregular lumps of a porous or bubbly structure, owing to the fermentation of the s. juice from long exposure to heat and its retention in a liquid condition. [a, 35.]—**Montpellier s.** Lat., *scammonium montepeliacum* (seu *montepeliacum, seu gallicum*). Fr., *scammonée de Montpellier* (ou *en galettes*). Ger., *französisches Scammonium, Scammonium von Montpellier*. French s., a factitious s. prepared from the expressed juice of a plant (*Cynanchum montepeliacum*, according to Guibourt) and various resins and purgatives. It is found usually in flat, semicircular cakes, blackish internally as well as externally, of a very bitter, nauseous taste and a feeble balsamic smell, not at all like that of real s. When rubbed with the moistened finger, instead of forming a white emulsion like s., it becomes dark-gray, unctuous, and tenacious. [B, 5, 180 (a, 35).] Cf. *Smyrna s.*—**Resin of s.** Lat., *resina scammonia* [Fr. Cod.] (seu *scammonia* [Belg. Ph., Ger. Ph. (1st ed.), Netherl. Ph., Russ. Ph., Swiss Ph.], seu *scammonis* [U. S. Ph., Fr. Cod., Swed. Ph.], from s.-root [Ger. Ph., Belg. Ph., Swiss Ph., Netherl. Ph., Russ. Ph.], or from either [Br. Ph.] with alcohol. The resin is freely soluble in ether, and does not form an emulsion with water. [B, 5, 18, 95 (a, 35, 38).]—**S.-root**. Lat., *scammonia* [Br. Ph., Netherl. Ph.], *scammonia radix* [Br. Ph., Netherl. Ph.], *radix scammonia* [Belg. Ph., Ger. Ph. (1st ed.), Russ. Ph.]. Sp., *escamonea (raíz)* [Sp. Ph.]. The dried root of *Convolvulus scammonia*. In some of the older classifications the term often included forms now referred to the Cyanophyceae. Owing to the inconstancy of forms, the limits of the species are not well defined. In Cohn's classification there are four principal groups: the spherical form (Micrococcus), the rod-like (Bacterium), the filament (Bacillus), and the coiled (Spirillum). Zopf divides them into the Cocciaceae, Bacteriaceae, Leptotrichae, and Cladotrichae. Ward, following De Bary, divides them provisionally into the Asporae, including the genera (Micrococcus [and Streptococcus], Sarcina [and Merismopedia], and Ascococcus) having no spores distinct from the vegetative cells; the Arthrosporeae, in which there are spores produced by segmentation differing in character from the vegetative cells (Arthrobaacteriaceae, Leptotrichae, and Cladotrichae); and the Endosporeae, including those forms (Bacillus, Spirillum [partly], etc.) in which spore-formation does not occur. **SELENIUM** (Lat.), n. n. Se<sup>2</sup>l-en(an)/i<sup>2</sup>-u<sup>2</sup>m(u<sup>2</sup>m). From *σελήνη*, the moon. Fr., *sélénium*. Ger., *Selen*. A non-metallic element discovered by Berzelius in 1817. It occurs in nature in combination with sulphur and with metals in many minerals. Ordinary, or soluble, s. is either a bright-red powder or a black micro-crystalline powder, soluble in carbon disulphide, and crystallizing from its solution in dark-red monoclinic crystals. When melted and quickly cooled it forms a dark-colored, translucent, vitreous, brittle substance. When melted, cooled to 210° C., and maintained at this temperature for some time, soluble s. is transformed into so-called metallic s., or insoluble s., a granular, crystalline mass, insoluble in carbon disulphide. S., when sublimed, gives off a dark-red vapor, which condenses into the so-called scarlet flowers of s. In composition s. is usually bivalent, replacing two atoms of hydrogen, but acts as a quadrivalent or sexvalent radicle. In the formation of its

compounds it presents a strong analogy with sulphur. Symbol, Se; atomic weight, 79. [B. 3.]—**S. bromide**. See *S. monobromide* and *S. tetrabromide*.—**S. chloride**.
